

Otoliths (fish ear stone): natural recorders of change in aquatic environments

Dr John Morrongiello
School of BioSciences
University of Melbourne

THE UNIVERSITY OF
MELBOURNE

Monitoring in Northern Australia

James Shelly

Dave Crook

Steve Parish

Tremendous biodiversity

Geographic isolation and biological novelty pose problems for traditional monitoring

Despite these challenges....

We need to understand what is going on

Majority of habitats are in good order

Natural and human-induced change

Fish are a key biological indicator

Social, cultural, and economic value

Play essential ecological role in aquatic environments

Sensitive to a range of drivers

Integrate system-wide response

Traditional fish monitoring

Provides point estimate of abundance

Requires long-term labour-intensive sampling

What is driving observed changes?

Often lacks a mechanistic underpinning

Can we monitor fish better?

Remotely

Cheaply

Process-based insight

Yes

Otoliths: let the fish do the work!

Otoliths- fish ear stone

Natural archives of biological information

When was a fish spawned?

How fast has it grown across its life?

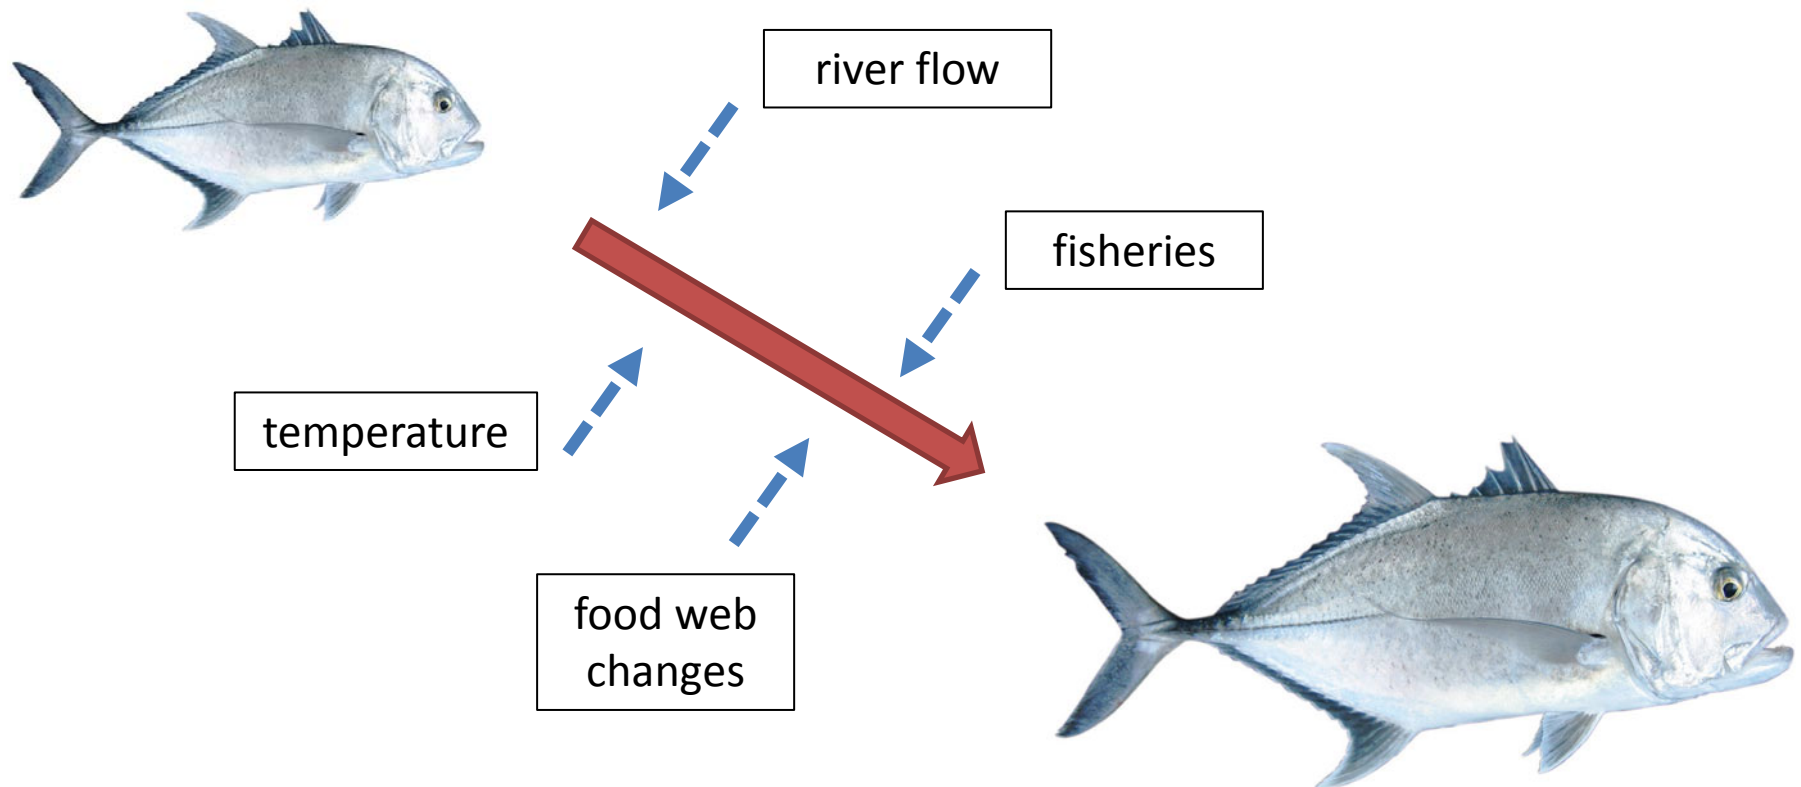

26 yo banded morwong

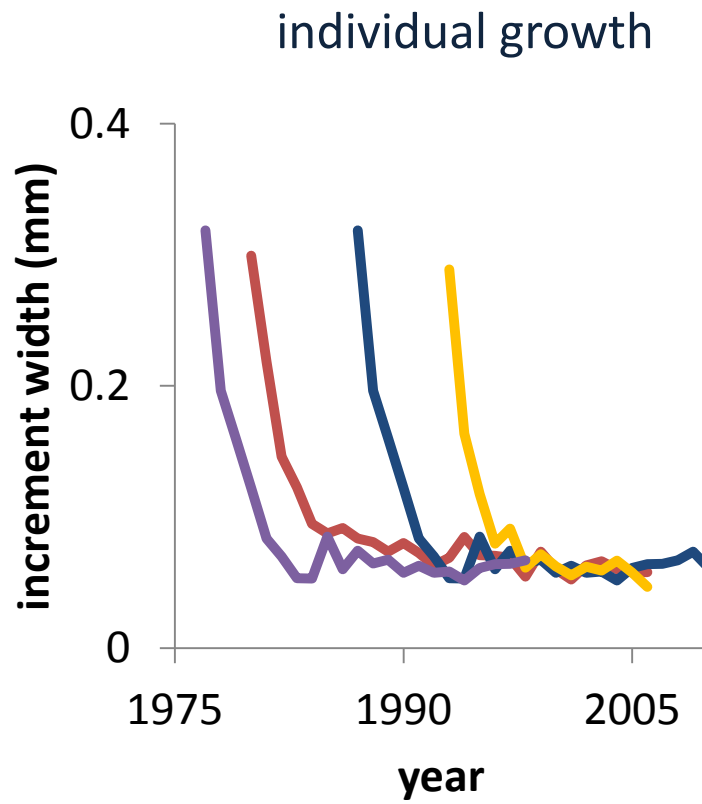

Growth as a biological indicator

Underpins individual fitness & population-level metrics

Sensitive to multiple drivers of change

Estuary perch

Flow and temperature driven
recruitment and growth dynamics

New South Wales Sydney

Canberra

Victoria

Melbourne

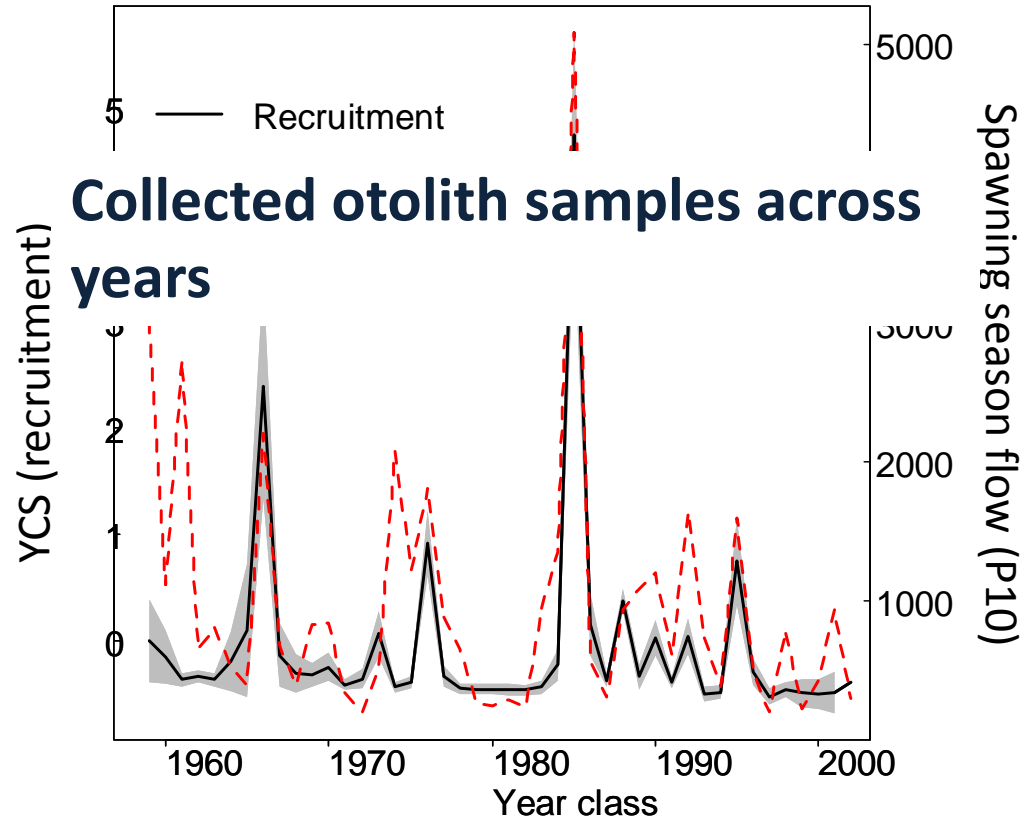

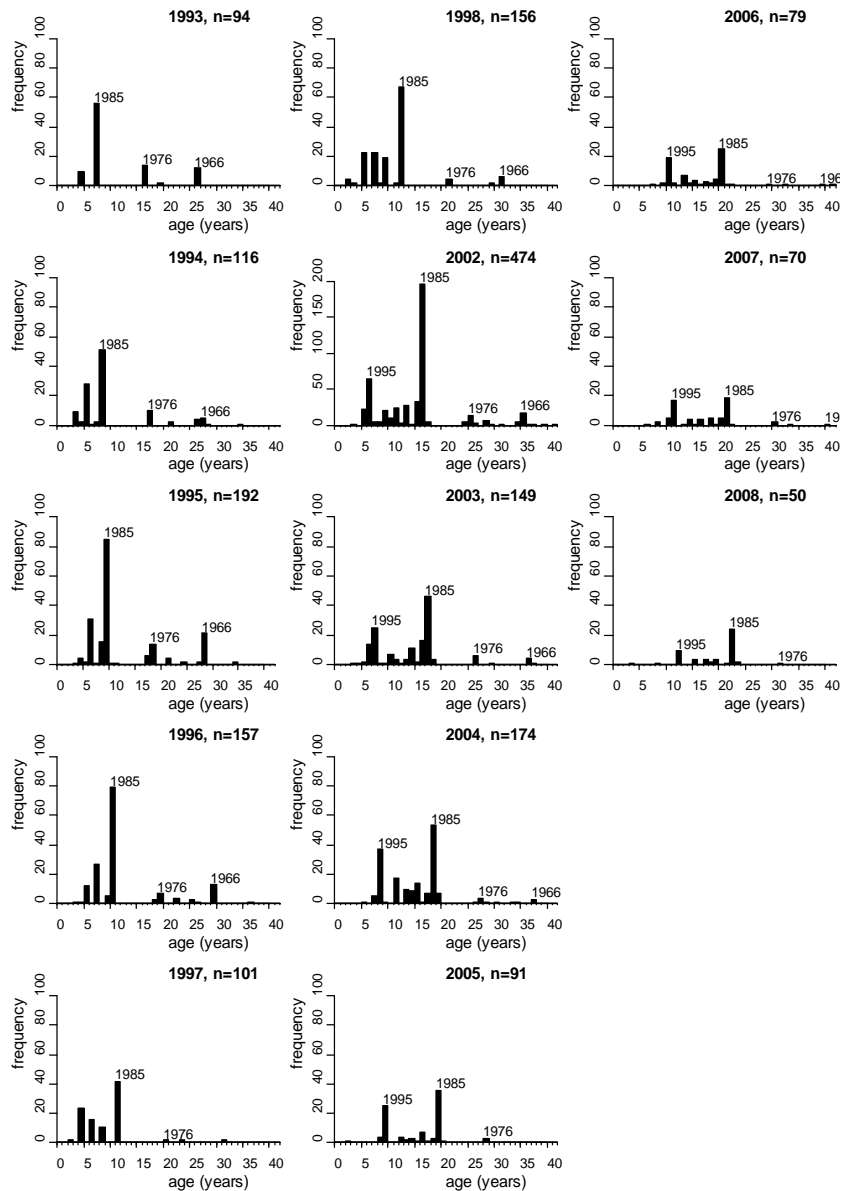

Bemm River

Bass Strait

Data SIO, NOAA, U.S. Navy, NGA, GEBCO

Google earth

Recruitment

High flows in spawning season
important for recruitment

Growth

Growth

Age-dependent temperature

Age-dependent flow

Biology is complex: traits respond to multiple and changing drivers
Models for prediction, e.g. response to flow changes

Current work:

“Influence of freshwater flows on growth and abundance of barramundi and mud crab in the Northern Territory”

Alison King, Dave Crook, Mark Grubert, Thor Saunders, Michael Douglas, John Morrongiello

Constraints

Need otoliths!

Destructive sampling of fish

Lagged detection of biological change (not real-time monitoring)

Model calibration

Benefits

Unprecedented
temporal resolution

Otolith collections
already exist- cheap
sampling

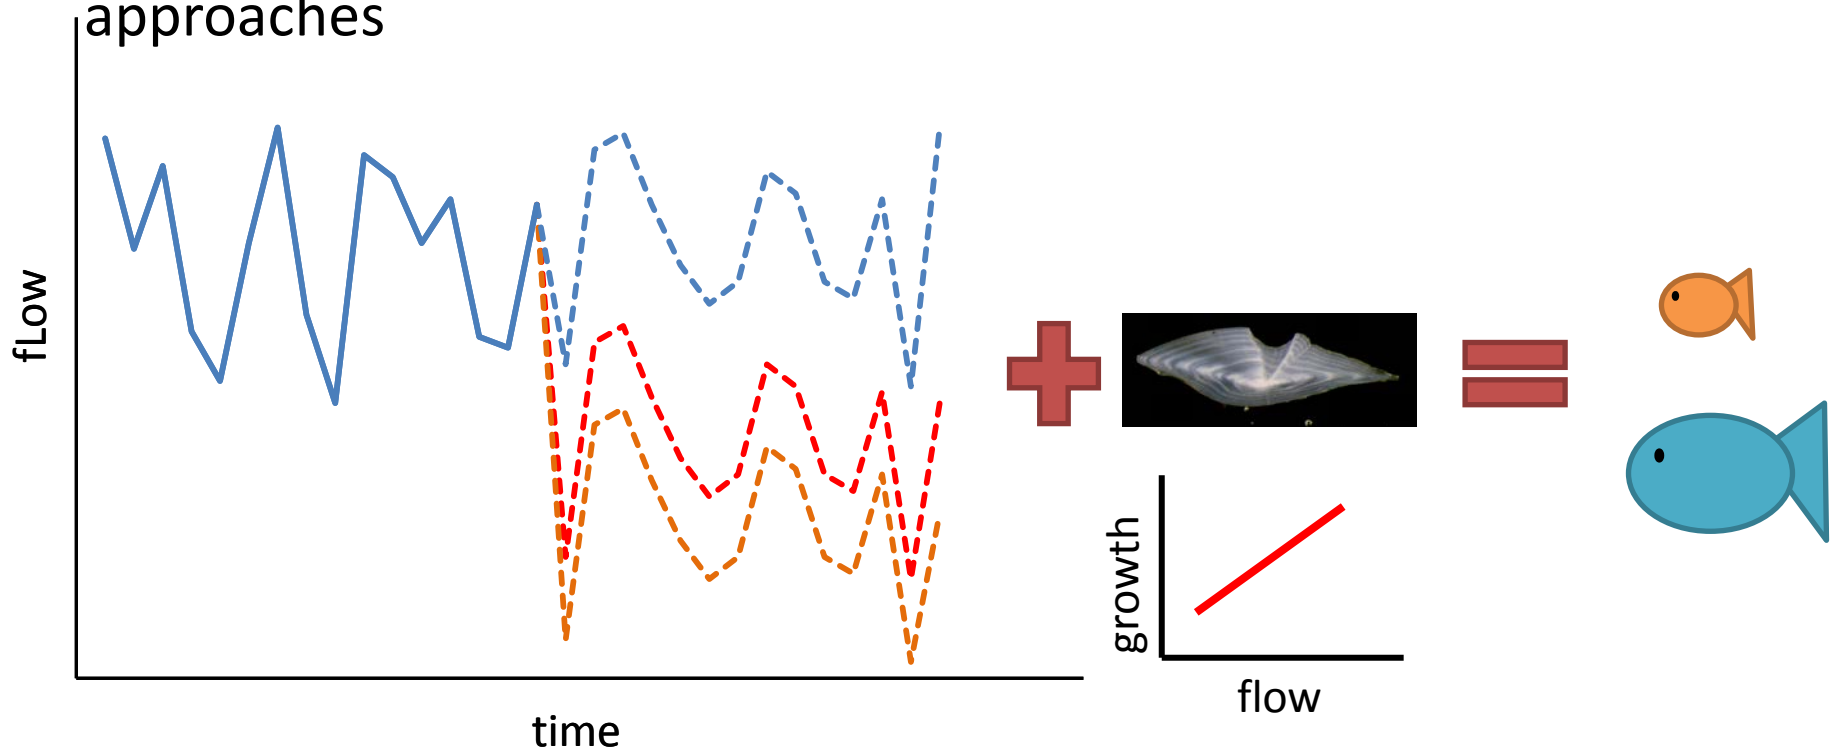

Benefits

Strong biological relevance of fish growth and recruitment

Predictive models: e.g., test impact of water extraction and river regulation scenarios; fisheries performance/ impacts

Key role in linking 'pattern to process'- complementary to other approaches

Thank you

Black bream

Recruitment driven by estuarine stratification

Low flows in spawning season important

Jenkins *etal* (2015) *Marine Ecology Progress Series* **523**: 125-144
